END OF SEARCH HISTORY

example, we can survey project managers about on-going projects and their characteristics in order to predict how much effort they will require. We can correlate the predictions with the outcomes to assess predictive criterion validity.

#### **Construct validity**

Construct validity concerns how an instrument "behaves" when used. We can think of this behavior in two ways. *Convergent* construct validity assesses the extent to which different data collection approaches produce similar results. *Divergent* construct validity assesses the extent to which results *do not correlate* with similar but distinct concepts. It often requires many years of experience to assess construct validity properly.

#### **Validity and Reliability in Software Engineering Surveys**

Generally, software engineering surveys are weak in the area of validity and reliability. For example, for many years, in the extensive literature relating to the CMM, there was only one reference to a reliability coefficient (the Cronbach's alpha) and that concerned the 1987 version of the Maturity Questionnaire [5]. Of the three surveys we discussed in part 1 of this series, only the Finnish Survey [8] made a concerted effort to undertake reliability and validity studies. Our own studies of technology adoption used face validity only. Lethbridge [6] and [7] discusses the basis for his questions, but his discussion of validity is based only on a post-hoc assessment of possible responder bias.

In contrast, the Finnish researchers used a panel of experts to judge the content validity of the questions. They also attempted to assess the internal reliability of their instrument. Unfortunately, they did not perform an independent pilot study. They analyzed their survey responses using principal components to identify strategies for managing risks. They then derived Cronbach alpha statistics [2] from the same responses. They found high values and concluded that their survey instrument had good reliability. However, Cronbach alpha values were bound to be high, because they measure the structure already detected by the principal component analysis.

#### **Survey Documentation**

After the instrument is finalized, Bourke and Fielder [1] recommend starting to document the survey. If the survey is self-administered, you should consider writing an initial descriptive document, called a *questionnaire specification*. It should include:

- The objective(s) of the study.
- A description the rationale for each question.
- The rationale for any questions adopted or adapted from other sources, with appropriate citations.
- A description of the evaluation process.

Furthermore, once the questionnaire is administered, the documentation should be updated to record information about:

- Who the respondents were.
- How it was administered.
- How the follow-up procedure was conducted.

- How completed questionnaires were processed.

One of the major reasons for preparing documentation during the survey is that surveys can take a long time. It may be many months between first distributing a questionnaire and when we are able to analyze results. It takes time for respondents to reply and for the researchers to undertake all necessary follow-up procedures. This time lag means that it is easy to forget the details of instrument creation and administration, especially if documentation is left to the end of the study. In general, it is good research practice to keep an experimental diary or log book for any type of empirical studies

When questionnaires are administered by interview, specifications are referred to as *interviewer specifications* and can be used to train interviewers as well as for reference in the field.

Once all possible responses have been received and all follow-up actions have been completed, we are in a position to analyze the survey data. In the next two articles, we discuss survey sampling and analysis issues.
